Using Objects

- a first example of an object
- classes and objects in Java
  - classes vs. objects
  - methods
  - constructing an object
  - mutators vs. accessors
  - object references
  - primitive values
  - Strings are special

Announcements

- The following students need to see me after class or in o.h. today:
  - missed the first class
  - not officially enrolled in class (e.g., on waiting list, trying to get in) (even if you attended first class)
  - have no previous programming experience

Our first object…

What are classes/objects?

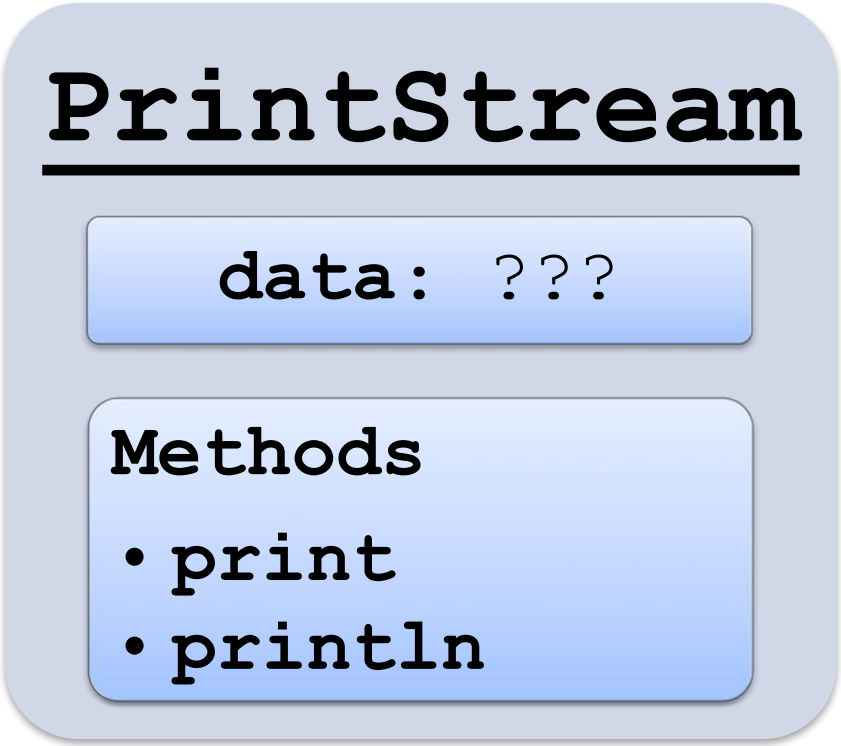
- just like functions are procedural abstractions…
  - give a name to an action
  - Examples: print(s), sqrt(x), sin(x), max(a,b)

- …classes are names for a data abstraction
  - encapsulates data + operations on that data (methods)
  - Examples: String, Watch, Car, Rectangle

What are classes/objects? (cont.)

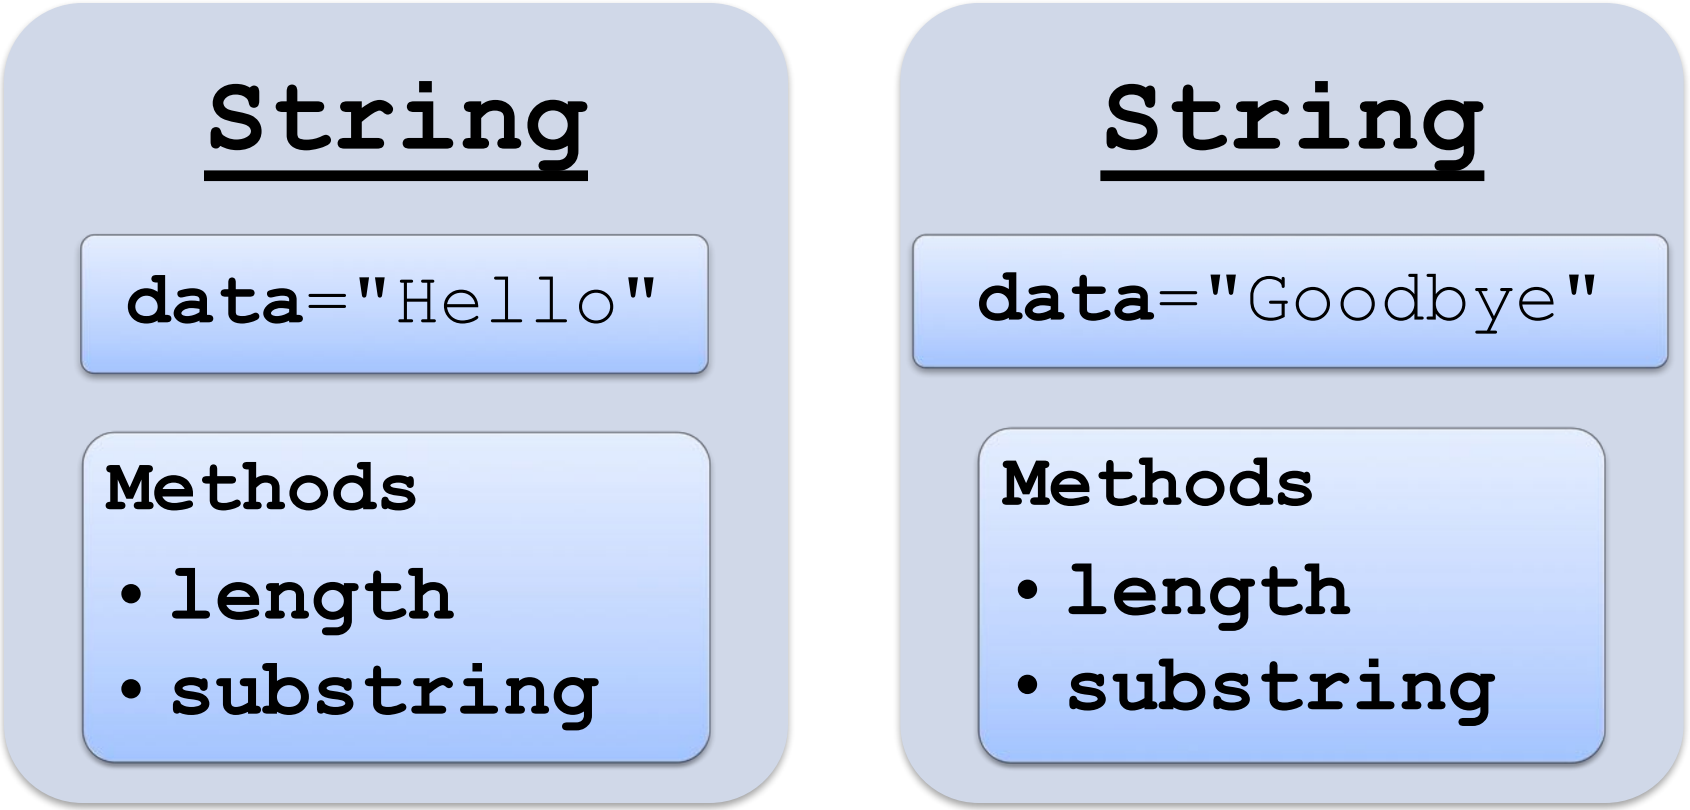
- with a class (data abstraction) **client** only knows…
  - name of class
  - what operations are
  - and how to use them

`System.out` object



```
System.out.println("Hello");
```

Multiple instances



```
String greeting = "Hello";
String lastWord= "Goodbye";
int n = lastWord.length();
```

More with Strings

Use vars below to create: **"Hello, Goodbye"**

```
String greeting = "Hello";
String lastWord = "Goodbye";
```

Constructing objects

- Before we can call methods, have to create the object.
- The following does *not* create an object:

```
Rectangle rect;
```

- This does…

```
Rectangle rect = new Rectangle(5, 10, 20, 30);
```

(parameters are: x, y, width, height)

- *constructor* call
- Can have multiple constrs. defined. e.g.,

```
rect = new Rectangle();
```

Accessors and Mutators

- 2 kind of methods
- **accessors**: examine object
  - examples:

    `hello.length(), rect.getWidth()`
  - almost always have a return value
  - often use **`get`** in name

Mutators

- **mutators**: modify object
  - may or may not have a return value
  - changes internal state of object
  - sometimes use **`set`** in name
  - example…

Mutator example

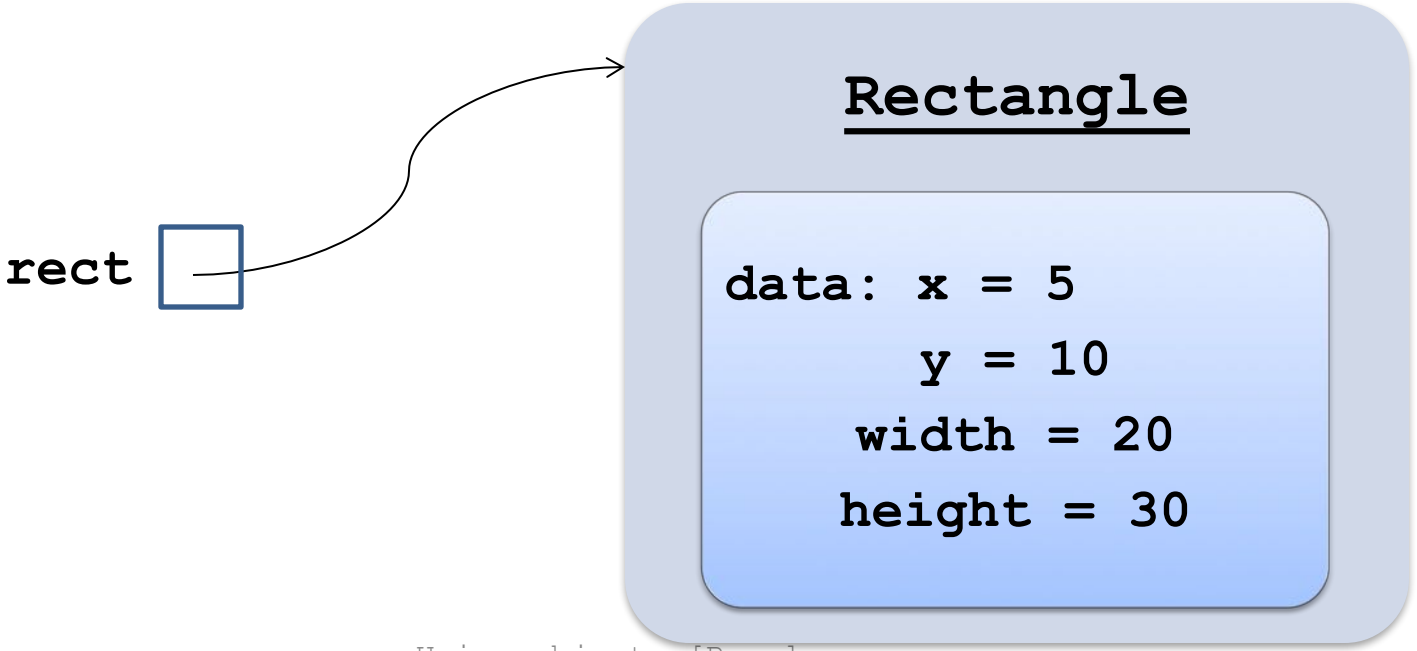
Example: **`rect.translate(deltaX, deltaY)`**

```
Rectangle rect =
        new Rectangle(5, 10, 20, 30);
rect.translate(10, 50);
```

Object references

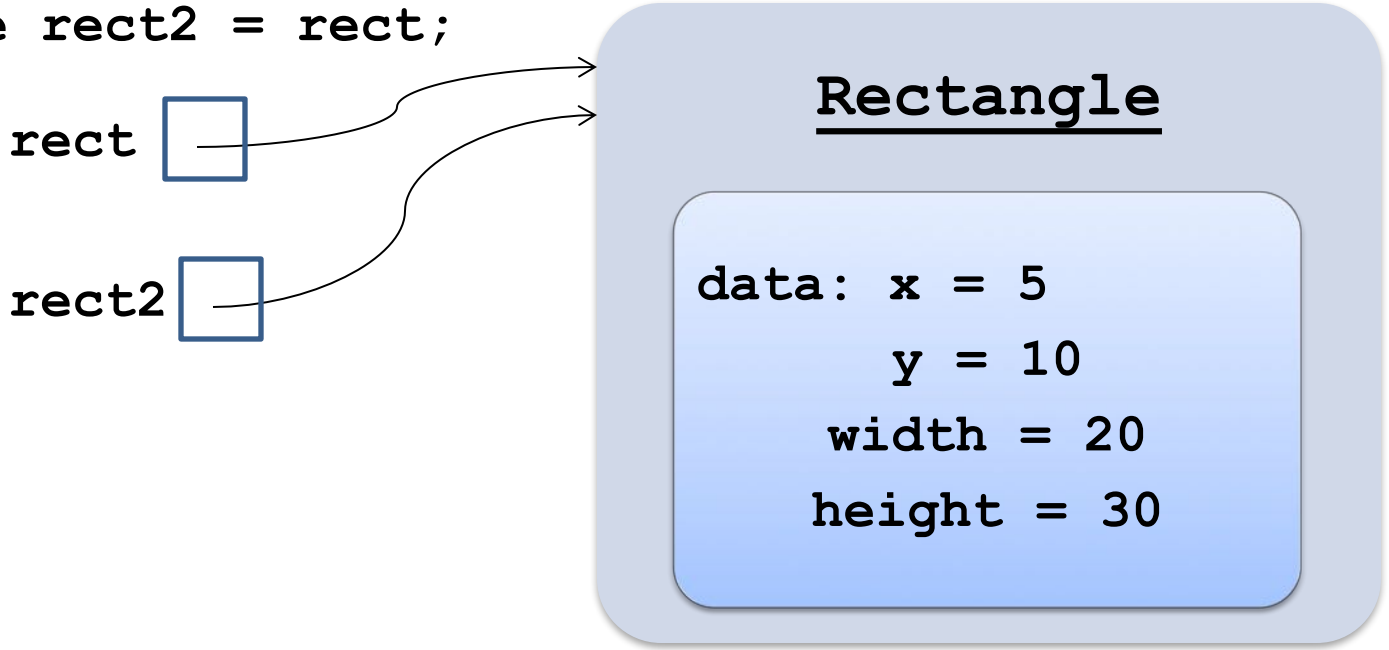
- variables of class types are not actually objects
- they are *object references*
- var contains the location of the object: *refers* to object
- e.g.

```
Rectangle rect = new Rectangle(5, 10, 20, 30);
```



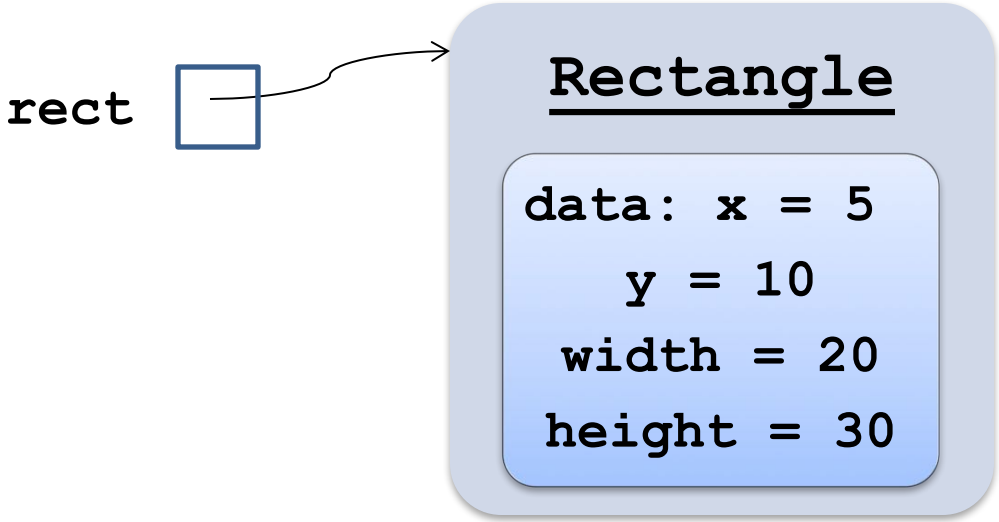
Two references to the same object

```
Rectangle rect = new Rectangle(5, 10, 20, 30);
Rectangle rect2 = rect;
```



Create two object instances

```
Rectangle rect = new Rectangle(5, 10, 20, 30);
Rectangle rect3;
```



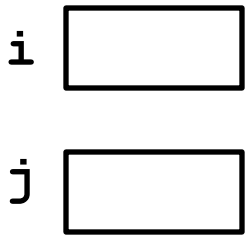
Same object vs. same value

- Can compare objects for equality two ways:
  - Do they have the same value? (**`equals`**)
  - Are they the same object? (**`==`**)
  - ```
    Rectangle rect = new Rectangle(5, 10, 15, 20);
    Rectangle rect2 = rect;
    Rectangle rect3 = new Rectangle(rect);
                                    // copy constructor
    ```
    ```

Objects vs. primitive values

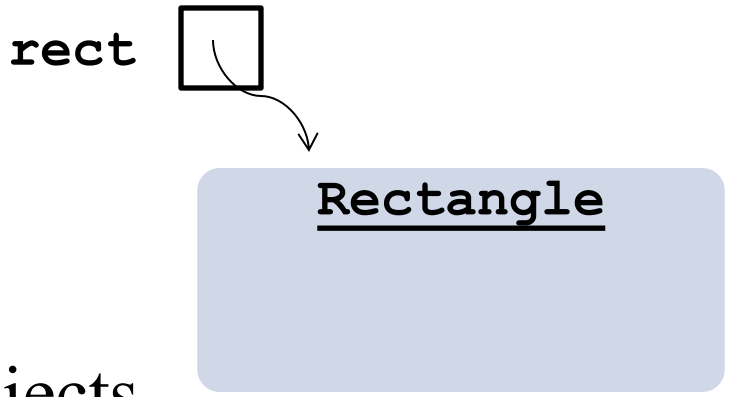
- 2 kinds of values: objects, primitive values
- primitive types: **`int, double, char`**, …

```
int i = 10;
int j = i;
j = 20;
```



- class types

```
Rectangle rect =
    new Rectangle(…);
rect2 = rect;
rect2.translate(…);
```



– assignment does *not* copy objects

`String` is special

- What about String?

```
String name = "Claire";
String name2 = name;
String name3 = "Claire";
```

- don't have to construct with new
- Strings may be shared internally for efficiency
- But it's safe: String is an *immutable* class

Immutable class

- Once object is created it's state can never be changed.
- Has no mutators.

Example `String` method

`s.substring(startCharLoc, oneAfterEndCharLoc)`

- count chars starting from 0

```
String name = "Claire";
```

- *oneAfter – start = length of substring created*

```
String bearHouse = name.substring(
```

`substring` is not a mutator

```
String name = "Claire";
String name2 = name;
String bearHouse = name.substring(1,5);
name2 = name2.substring(2,5);
System.out.println(name + " " + name2);
```

Complete program in **~csci455/code/01-12/StringEx.java**

`String` is special: summary

- Strings instances are objects: have methods
- But can treat them more like numeric values:
  - don't need **`new`** to create one:

    ```
    String a = "foo";
    ```

  - assignment works as if it "copies" the String

    ```
    String b = a;
    ```

  - has "overloaded" Java + operator:

    ```
    a + b
    ```

  - can't change a String value once created:
    - **`charAt`**, **`replace`**, **`substring`**, etc. return new strings
